5. Open the FTP connection from the previous step.	33
6. Copy saved_model.tflite and signature.json from your exported Lobe model to the model directory on	the Pi.
7. In terminal on the Pi, run the following script to install Lobe and all it's dependences:	3434
8. In terminal on the Pi, run the Python program lobe-basic-prediction.py	34
Going Further	35

### Overview

Welcome to the wonderful world of Lobe, where you can train Machine Learning models without writing a single line of code!! Lobe is free and easy-to-use, all you have to do is take pictures and label them and Lobe does the rest.

In this guide we'll walk through training a Lobe model, exporting it, and running it on a Raspberry Pi 4.

This tutorial is part of a series which include the following tutorials:

- Tutorial 2 Build an ML Rock Paper Scissors Game with Lobe (https://adafru.it/RiB)
- Tutorial 3 Build an ML Package Detector with Lobe (https://adafru.it/RiA)

### Background Knowledge

To be successful with this project, you'll need some experience with the following:

- 1. Setting up and using the Raspberry Pi
- 2. Some familiarity with using the terminal window
- 3. Installing the Pi Camera

## **Required Parts**

#### Microsoft Machine Learning Kit for Lobe with Raspberry Pi 4 4GB

Machine learning is a transformative tool that's redefining how we build software—but up until now, it was only accessible to a small group of experts. At Adafruit, we...

#### Out of Stock

## Train a Model with Lobe

First, we'll train a custom machine learning model using objects on your desk. For my model I used a pen, Lobe sticker, and a succulent plant. Feel free to use any objects you'd like!

First, download and install Lobe from the link below:

1. Open Lobe and create a new project.

Aachine .earning 101	Label			Import
🖞 Label				Images Import images from your computer.
⑦ Train ⑦ Use			1	Camera Capture images with your webcam.
All Images 0		ZAK	To start tr	Dataset Import a structured folder of images.
Dne 0		TE	import and lab	pel some images.
Fwo 0		A	Learn More	Watch Tour
5 images per label				

# 2. In the Label tab, select Import (top right corner), and Camera from the drop down menu.

If this is your first time using Lobe you'll need to give it permission to use your camera.

### 3. In the bottom left corner, type a label for the first image.

My first label is "Pen" because it's a picture of, well, a pen!

# 4. Take between 10 and 20 pictures of your objects using your computer's camera.

Take pictures from different angles, in different lighting conditions, and with different hand placements to improve model accuracy.

### 5. Repeat steps 3 and 4 for the rest of your objects.

Remember to add a new label for each object (e.g. "Sticker" and "Succulent").

Machine .earning 101	Import
5 Label	
Training	
🛇 Use	
All Images 20	
Nothing 5	and the second se
Pen 5	and a second
Sticker 5	
Succulent 5	
Lobe is starting to train your model	Nothing

### 6. Add a "Nothing" category.

This improves accuracy of the ML model. See below for more info.

Why is there always a prediction even when nothing is in the image?

Lobe will always predict one of your labels even if your image does not contain any related content. If you expect your model to see these types of images, create a '*None*' label and add variations of these images as examples. You can use this 'None' label as a placeholder when waiting for relevant predictions.

## Test your Model

In Lobe, training happens automatically as soon as you add enough images (a minimum of 5 for each label).

When you have taken between 5 and 10 pictures of each object and training is complete, test out the model by following the steps below.

### 1. In Lobe, select the Use tab and choose Camera.

1a. This is the ML model prediction. The more full this bar is, the more confident the algorithm is with the prediction.

2. Try different placements of the objects used for training and see how the model performs.

Try other objects of the same type to check model accuracy. Also try out multiple objects at once. You will notice Lobe only makes one prediction at a time, even if there are multiple objects. See if you can trick your model into predicting the wrong thing and find ways to improve it.

### 3. Improve your model using the buttons in the bottom right.

My model did a great job at identifying sticky notes, but it mixed up the pen and highlighter.

1b. Use these buttons to give Lobe feedback to improve your model.

Click the green button for images that the model predicts correctly. Select the red button for images the model predicts incorrectly.

## Export your Model

Next, export your Lobe model to use on the Raspberry Pi. We'll use **TensorFlow Lite** which is a format that is optimized for mobile and edge devices, like the Pi.

In Lobe, navigate to the Use tab and click Export.

Select TensorFlow Lite and select a location to save the model. We'll transfer the model to our Raspberry Pi later in the tutorial.

## Set up Raspberry Pi and BrainCraft

Now that the ML model is working on your computer, let's get your Raspberry Pi and BrainCraft HAT ready to make predictions on new images (also called **inferencing**). Your kit includes all the parts you need for this.

The next few steps walk you through setting up your BrainCraft HAT. We will skip audio setup since we aren't using it for this project, but if you can find the complete setup guide <u>here (https://adafru.it/NLE)</u>.

Please note that the following steps require installing a lot of packages on the Pi and it may take a few hours to download everything.

Logging into your Pi in a headless configuration via SSH? Use the "raspberrypi.local" IP (more info below)

As long as you're on the same WiFi as the Pi, you can use the IP address raspberrypi.local, as shown below:

ssh pi@raspberrypi.local

## Raspberry Pi Setup

OK now you have all your parts in order, it's time to get your Raspberry Pi computer set up with the HAT or Bonnet.

## Step 1 - Burn SD Card

<u>Use Etcher or the Raspberry Pi Imager</u> (https://adafru.it/dDL) to burn the latest **Raspbian Lite to an SD** card (you can use full but we won't be using the desktop software and it takes up a bunch of room.

## Step 2 - Configure log-in access

You'll need to be able to log into your Pi, <u>either enable SSH access (and use and Ethernet</u> <u>cable)</u> (https://adafru.it/jvB), use a USB to serial cable, or connect a monitor and keyboard. Basically get it so you can log in.

#### We have a quickstart guide here (https://adafru.it/NmF) and here that you can

<u>follow</u> (https://adafru.it/DQA), or there's dozens of online guides. it is assumed by the next step you are able to log in and type commands in - ideally from a desktop computer, so you can copy and paste in some of the very long commands!

## Step 3 - Log in & Enable Internet

Once you've logged in, <u>enable WiFi (if you have built in WiFi) with</u> sudo raspi-config (https://adafru.it/v7D) so you can ssh in.

Enable SSH as well if you haven't yet, also via sudo raspi-config

After you're done, reboot, and verify you can log into your Pi and that it has internet access by running ping -c 3 raspberrypi.org and seeing successful responses.

pi@rasp	perrypt	:~ \$	ping -c 3	raspbe	rrypi.org				
PING ras	spberry	/pi.org	g (93.93.	135.117	) 56(84) l	bytes of da	ta.		
64 bytes	s from	93.93.	.135.117	(93.93.1	135.117):	icmp_seq=1	ttl=56	time=85.1	ms
64 bytes	s from	93.93.	.135.117	(93.93.1	135.117):	icmp_seq=2	tt1=56	time=87.6	ms
64 bytes	s from	93.93.	.135.117	(93.93.1	135.117):	icmp_seq=3	ttl=56	time=91.1	ms
ras	oberry	oi.org	ping sta	tistics					
3 packet	ts tran	nsmitte	ed, 3 red	eived, (	0% packet	loss, time	5ms		
rtt min,	/avg/ma	ax/mdev	v = 85.05	6/87.92	7/91.094/2	2.485 ms			
pi@raspl	perrypt	:~ \$							

### Step 4 - Update/Upgrade

Now that you are logged in, perform an update/update:

sudo apt update

sudo apt-get update

#### sudo apt-get -y upgrade

and

sudo apt-get install -y python3-pip

sudo pip3 install --upgrade setuptools

OK you've now got a nice, clean, connected, and up-to-date Pi!

## Blinka Setup

Blinka is our CircuitPython library compatibility layer. It allows many of the libraries that were written for CircuitPython to run on CPython for Linux. To learn more about Blinka, you can check out our <u>CircuitPython on Linux and Raspberry Pi</u> (https://adafru.it/BSN) guide.

We put together a script to easily make sure your Pi is correctly configured and install Blinka. It requires just a few commands to run. Most of it is installing the dependencies.

```
cd ~
sudo pip3 install --upgrade adafruit-python-shell
wget https://raw.githubusercontent.com/adafruit/Raspberry-Pi-Installer-Scripts/master/raspi-
blinka.py
sudo python3 raspi-blinka.py
```

When it asks you if you want to reboot, choose yes.

Raspberry Pi and installs Blinka

Blinka Building dependency tree	
Blinka Reading state information	
Blinka pythons-pip is already the newest version (18.1-5+rpt1).	
Blinka o upgradea, o newly installed, o to remove and o not upgraded.	

Finally, once it reboots, there are just a couple CircuitPython libraries to install for the BrainCraft HAT or Voice Bonnet.

The DotStar library is for controlling the 3 on-board DotStar LEDs and the Motor library is for testing out the GPIO pins.

pip3 install --upgrade adafruit-circuitpython-dotstar adafruit-circuitpython-motor adafruitcircuitpython-bmp280

<pre>pi@raspberrypi:~ \$ pip3 installupgrade adafruit-circuitpython-dotstar adafruit-circu</pre>
itpython-motor adafruit-circuitpython-bmp280

Requirement already satisfied, skipping upgrade: Adafruit-PureIO>=1.1.6 in /usr/local/l
ib/python3.7/dist-packages (from Adafruit-Blinka->adafruit-circuitpython-dotstar) (1.1.

That's it for Blinka and CircuitPython libraries.

## Fan Service Setup

We have a really simple fan service that will control the onboard fan. The reason we have it set up as a service instead of keeping the fan on all the time is so that it doesn't drain too much power from the Pi during the initial power on.

The fan service basically controls turning GPIO 4 on at startup, which is what the fan is connected to. Installing the fan service is really simple and we have a script for doing that.

To install, just type sudo raspi-config

#### Select Performance Options

🛅 pi@raspberrypi: ~	-	- 5	) ×	
Raspberry Pi 4 Model B Rev 1.1				^
Raspberry Pi Softw	are Configuration Tool (raspi-config)			
1 System Options 2 Display Options	Configure system settings Configure display settings			
3 Interface Options 4 Performance Options	Configure connections to peripherals	;		
5 Localisation Options 6 Advanced Options 8 Update 9 About raspi-config	Configure language and regional set Configure advanced settings Update this tool to the latest vers Information about this configuration	ion 1 tool		
<select></select>	<finish></finish>			
				$\lor$

#### Select Fan

#### Select Yes

And make sure you put down GPIO pin 4 for the fan

To which GPIO is the	fan connected?	1
4		
<0k>	<cancel></cancel>	

You can customize the fan temperature setting

At what	temperature	in degrees	should the fa	n turn on?
80				
	<0k>		<cancel></cancel>	

That's it!

You can then 'stress test' by running

- sudo apt-get install stress
- while true; do vcgencmd measure\_clock arm; vcgencmd measure\_temp; sleep 10; done& stress -c 4 -t 900s

pi@raspberrypi:~ \$ while true; do vcgencmd measure_clock arm; vcgencmd measure_t
emp; sleep 10; done& stress -c 4 -t 900s
[1] 955
stress: info: [956] dispatching hogs: 4 cpu, 0 io, 0 vm, 0 hdd
frequency(48)=600169920
temp=53.5'C
frequency(48)=1500345728
temp=60.8'C
frequency(48)=1500398464
temp=64.2'C
frequency(48)=1500398464
temp=65.7'C
frequency(48)=1500398464
temp=66.7'C
frequency(48)=1500345728
temp=66.2'C
frequency(48)=1500398464
temp=68.6'C

When the temperature hits the limit you set earlier, the fan should turn on, and cool the pi back down (in this case I set it to 70 C):

pi@raspberrypi:~ \$ while true; do vcgencmd measure_clock arm; vcgencmd measure_t	
emp; sleep 10; done& stress -c 4 -t 900s	
[1] 684	
stress: info: [685] dispatching hogs: 4 cpu, 0 io, 0 vm, 0 hdd	
Frequency(48)=600117184	
temp=59.4'C	
Frequency(48)=1500398464	
temp=66.2'C – Fan turns on here	
Frequency(48)=1500345728	
temp=70.1'C	
frequency(48)=1500345728	
temp=68.1'C	
frequency(48)=1500398464	
temp=68.6'C	
Frequency(48)=1500345728	
temp=66.2'C	
Frequency(48)=1500398464	
temp=66.2'C	
	$\mathbf{v}$

## Fan Service Troubleshooting

On some newer versions of Raspberry Pi OS the Fan service fails to start. Luckily these newer version of the OS have a built in fan control you can turn on.

In command prompt or terminal connect to the pi using SSH and run the command:

#### sudo raspi-config

🖬 pi@raspberrypi: ~ 🛛	×
Raspberry Pi 4 Model B Rev 1.2	^
Raspberry Pi Software Configuration Tool (raspi-config)	
1 System OptionsConfigure system settings2 Display OptionsConfigure display settings3 Interface OptionsConfigure connections to peripherals4 Performance OptionsConfigure performance settings5 Localisation OptionsConfigure language and regional settings6 Advanced OptionsConfigure advanced settings8 UpdateUpdate this tool to the latest version9 About raspi-configInformation about this configuration tool	
<select> <finish></finish></select>	

#### Select Performance Options

🔤 pi@raspberrypi: ~				_		×
P1 Overclock P2 GPU Memory P3 Overlay File P4 Fan	Pi Softwar Con Chi System Ena Set	re Configuration Tool nfigure CPU overclocki ange the amount of men able/disable read-only t behaviour of GPIO fa	(raspi-co ng nory made file sys n	nfig) availa tem	⊨	^
	<select></select>	<back< td=""><td>&gt;</td><td></td><td></td><td>v</td></back<>	>			v

#### Select Fan

The default GPIO pin is 14, but the BrainCraft Hat has the fan connected to pin 4.

🔤 pi@raspberrypi: ~ 🛛 —	×
	 ^
At what temperature in degrees should the fan turn on?	
80	
<ok> <cancel></cancel></ok>	
	$\sim$

You can set the temperature to anything between 60-120 degrees Celsius. 80 is a good midway point in that range.

You'll need to reboot after changing the settings.

Now your fan will come on when ever the board is over 80 degrees. To check the current temperature of your board you use this command:

/opt/vc/bin/vcgencmd measure\_temp

## **Display Module Install**

There's two ways you can use the 1.54" 240x240 display on the BrainCraft HAT. For machine learning purposes, the advanced method is the way to go, so that's what we'll be covering in this guide.

Be aware that you can only choose to do one way at a time. If you choose the advanced way, it will install the kernel driver, which will prevent you from doing it the easy way without uninstalling the driver first.

**The easy way** is to use 'pure Python 3' and Pillow library to draw to the display from within Python. This is great for showing text, stats, images etc that you design yourself. If you want to do that, the BrainCraft HAT has a pretty close layout to the <u>Adafruit 1.3" Color TFT Bonnet</u> (https://adafru.it/NFh) including the same type of display and a joystick, though the pinouts are slightly different. If you choose this option, You can skip this page and view the <u>Python Setup page</u> (https://adafru.it/NFi) for instruction for that display.

The advanced way is to install a kernel module to add support for the TFT display that will make the console appear on the display. This is cute because you can have any program print text or draw to the framebuffer (or, say, with pygame) and Linux will take care of displaying it for you. If you don't need the console or direct framebuffer access, please consider using the 'pure Python' technique instead as it is not as delicate.

If you plan on using the Pi Camera for vision projects, you will need to go with the advanced route!

## Installing The 1.54" Kernel Module

We have tried to make this as easy as possible for you by providing a script that takes care of everything. There's only a couple of dependencies needed. To get everything setup, just run the following at the terminal:

```
cd ~
sudo pip3 install --upgrade adafruit-python-shell click
sudo apt-get install -y git
git clone https://github.com/adafruit/Raspberry-Pi-Installer-Scripts.git
cd Raspberry-Pi-Installer-Scripts
sudo python3 adafruit-pitft.py --display=st7789_240x240 --rotation=0 --install-type=fbcp
```

If you want to use the BrainCraft HAT for vision projects, you will need to install the display driver as FBCP and not console.

When you get asked to reboot, reboot!

That's it! You will now have the BrainCraft HAT with a console display on it

## Kernel Module Troubleshooting

The Raspberry Pi Kernel sometimes updates firmware, which can which can break the Frame Buffer Copy mechanism. In this particular case, it only seems to affect the Raspberry Pi 4. The issue appears as a garbled screen that looks like static.

To check your kernel version, run the following command:

dpkg -l raspberrypi-kernel

You should see output similar to the following. If the kernel version is later than 1: 1.20210527, then the following fix should work.

pi@raspberrypi:~ \$ dpkg	g -l raspberrypi	i-kernel	
Desired=Unknown/Install	/Remove/Purge/H	Hold	
Status=Not/Inst/Conf-	files/Unpacked	/halF-conf/Hal	lf-inst/trig-aWait/Trig-pend
<pre>// Err?=(none)/Reinst-r</pre>	required (Status	s,Err: upperco	ase=bad)
II/ Name	Version	Architecture	Description
+++-===================================			
ii raspberrypi-kernel	1:1.20210831-1	armhf	Raspberry Pi bootloader

We have a script that is able to set the kernel version to the kernel version prior to it breaking. To "pin" the kernel version to an older version prior to it breaking, you'll need to run a few commands. You can either SSH into the Pi or hook up an HDMI cable, though the display may appear small.

Once you'd at a command prompt, run the following commands. Note that the 1: prefix in the version number is on purpose because of the way that pinning was recently changed.

```
cd ~
wget https://raw.githubusercontent.com/adafruit/Raspberry-Pi-Installer-Scripts/master/rpi-pin-
kernel-firmware.sh
sudo sh rpi-pin-kernel-firmware.sh 1:1.20210527-1
```

After it finishes, reboot the Pi.

Once the Pi is back up, the display may appear inverted. To fix this, just run the Adafruit PiTFT script again and reboot a second time.

You can check the new kernel version by running the dpkg command again:

dpkg -l raspberrypi-kernel

This time, your version should be 1:1.20210527-1.

### BrainCraft Audio Driver Reinstall

If your display is a BrainCraft HAT and you have pinned your kernel, you should be running a kernel version of around 5.10. You can check this by typing uname -r.

If you pinned to an older version that uses a kernel of 5.4, you may need to reinstall the audio drivers at this point to get sound working. Be sure to follow the <u>BrainCraft HAT Audio Setup</u> <u>instructions</u> (https://adafru.it/Pf8) for a kernel version around 5.4 when reinstalling.

### Unpinning the Kernel

To unpin the kernel, just delete the file /etc/apt/preferences.d/99-adafruit-pin-kernel and update the Pi with the following commands:

sudo apt update
sudo apt upgrade

## Camera Test

### Install the Pi Camera module

Make sure you have the Pi camera module by running the following command:

pip3 install picamera

Now that you have everything set up, it's time to do an initial test with the camera. This should display what the camera sees on the display.

#### raspistill -t 0

Exit the camera test by pressing CTRL + C

## Set up an FTP Connection

Since we're using the Pi in a headless configuration, we'll use an FTP connection to transfer files between our computer and the Pi.

### Windows Instructions

Download and install WinSCP (https://adafru.it/OcF)

## Get Predictions on the Pi

### 1. Connect your Pi to a power source and wait for it boot up.

You should see a solid red light and an intermittently flashing green light.

# 2. Open **command prompt** on a PC or terminal on Mac/Linux and connect to your Pi using SSH.

Type the following command but replace the bolded number below with IP address of your Pi:

ssh pi@192.168.0.22

Your Pi's IP address is on the screen of the BrainCraft. You can also use the hostname address, e.g. "raspberrypi.local" (pi@raspberrypi.local)

### 3. Download the GitHub folder.

Run the following commands to download the sample code from GitHub:

```
cd ~
git clone https://github.com/lobe/lobe-adafruit-kit.git
```

### 4. Create a new folder called model in the home directory.

Type the following commands:

cd ~ mkdir model	
	🦾 WinSCP
	Local Mark Files Commands Session Op
	New Session
	🛛 🔄 Upload 🗸 📝 Edit 🥆 🗙 🛃 🕞 Prop

5. Open the FTP connection from the previous step.

5.7 MD 01 99.7 MD IN 2 01	3			0 0 01 99.7 Mib in 0 01 2			

6. Copy saved\_model.tflite and signature.json from your exported Lobe model to the model directory on the Pi.

7. In terminal on the Pi, run the following script to install Lobe and all it's dependences:

```
cd ~
wget https://raw.githubusercontent.com/lobe/lobe-python/master/scripts/lobe-rpi-install.sh
sudo bash lobe-rpi-install.sh
```

### 8. In terminal on the Pi, run the Python program lobe-basic-prediction.py

Type the following commands:

```
cd ~
cd lobe-adafruit-kit
python3 lobe-basic-prediction.py
```

## **Going Further**

predicted corre	ectly.			

Keep testing the model on the Pi and see how it works. If you find that the prediction is consistently wrong, you can add more images to the model to improve its performance.

You can train an ML model to recognize all sorts of objects and then use the BrainCraft to trigger actions in the physical world!

To learn how to do this, check out these more advanced projects:
